

Project Kelen Milestone Report to the The Shareholders

The project kelen aims at aiding secondary schools in the rural regions of Cameroon by providing internet access, bilingual lessons with local languages inclusive as well as tracking the growth of the students progress.

This project is built with a flutter mobile app, a fast API backend and an offline neural translation engine running on-device.

Furthermore, the team just completed and tested a fix for a crash that was happening on Android devices when students opened the progress dashboard.

This project as earlier mentioned unlocks offline translation for two additional local languages making it a

sum of 12 to hit the original
target of 24 languages by the
end of the term.

Project Kelem Milestone Report To Product owner

Presented by: Group Two
Date: 18 July 2026

Project Kelem's latest milestone successfully advances software reliability and offline language expansion. The development team resolved an Android dashboard crash caused by large session duration values by implementing value sanitization and a fall back mechanism, verified on multiple devices.

Additionally, offline translation support was for two new local languages, bringing the total to twelve and maintaining the ~~pace~~ pace towards the glory of twenty four languages.

* A key ^{cap} pending decision remains regarding whether to ^{cap} session-duration values during data recording or display, which will impact historical data management. Next steps include implementing the technical leads decision on data handling, integrating more languages and conducting further reliability testing to keep the project on track.

Project Kelem Milestone Report to the Technical Lead.

Date: 18 July 2026

The team just completed and tested a fix for a crash that was happening on Android devices when students opened the progress dashboard. The root cause was an integer overflow in the Charting library used to render weekly progress graphs. Very large session-duration values were breaking the chart rendering.

The fix caps and sanitizes duration values before they reached the chart added a fallback so the dashboard ~~doesn't~~ does not crash even if bad data slips through. It was tested on 3 Android devices and 1 low-end tablet, matching hardware similar to what schools use.

Even though we have those successes, one remaining open question is should the session data be capped at the source or only ~~sanitized~~ sanitized before display? That decision ~~re~~ really affects how historical data already stored is handled.
